# 1 Subtyping https://eduassistpro.github.io/

of floating point values and integer values, and the compiler will figure out which to use. However, the following expression would still be rejected by the MinHs compiler:

Assignment Project Exam Help

This is Act is light and periodically late to convert the Int value to Float to add the two values.

C solves this probl c types are ordered and if operations like the hierarchy is auton at the compact of the little that the li

The idea behind subtyping is similar to the approach in C in that types can be partially ordered in a subtype relationship

 $\tau \leq \sigma$  Add WeChat edu\_assist\_pro

such that, whenever a value of some type  $\sigma$  is required, it is also fine to provide a value of type  $\tau$ , as long as  $\tau$  is a subtype of  $\sigma$ . For example, we could have the following subtype relationship:

 ${\tt Int}\,\leq\,{\tt Float}\,\leq\,{\tt Double}$ 

With subtyping, it would then be ok to have

 $1 +_{Float} 1.75$ 

as floating point addition wants to floating point values, but also accepts Ints, as they are a subtype of Float.

#### 1.1 Coercion Interpretation

There are different ways to interpret the subtype relationship: one would be to define  $\tau$  to be a subtype of  $\sigma$  if it is a actual subset. For example, in the mathematical sense, integer numbers are a subset of rational numbers, even integral numbers of integral numbers and so on. However, this interpretation is quite restrictive for a programming language: Int is not a subset of Float, as they have very different representations. However, there is an obvious *coercion* from Int to Float.

<sup>&</sup>lt;sup>1</sup>In Haskell, this expression by itself would be fine, as constants are also overloaded and 1 has type  $Num\ a \to a$ . However, the compiler would also reject the addition of integer and float values, for example (1::Int) + (1.7::Float).

For our study of subtyping, we will focus on this so-called *coercion interpretation* of subtyping:  $\tau$  is a subtype of  $\sigma$ , if there is a *sound*  $^2$  coercion from values of type  $\tau$  to values of type  $\sigma$ .

As another example, consider a **Graph** and **Tree** type. Since trees are a special case of graphs, trees can be converted into a graph and we can view the tree type as subtype of the graph type in the coercion interpretation.

#### 1.2 Properties

For a subtyping relationship to be sound, it has to be reflexive, transitive, and antisymmetric (with respect to type isomorphism). This means it is a partial order. This is the case for both the subset as well as the coercion interpretation. For the subset interpretation, all three properties follow directly from the properties of the subset relation. In the coercion interpretation, reflexivity holds because the identity function is a coercion from  $\tau$   $\tau$ . Transitivity holds since, given a coercion function from f ult in a coercion

function from  $\tau_1 \to \tau_3$ . In order to guarantee that  $\tau_3$ . In order to guarantee that  $\tau_3$ . In order to guarantee that  $\tau_4$  is must mean that if we can coerce  $\tau$  to  $\rho$  and  $\rho$  back to  $\tau$ , this must mean  $\tau \simeq \rho$ . This is only true if the coercion functions are injective — that is, we can map each element of the domain (input) of the function a surjective depreciate that  $\tau_4$  is the function of the function as  $\tau_4$  is the function of the function as  $\tau_4$  is the function of the function as  $\tau_4$  is the function of the function of  $\tau_4$  is the function of  $\tau_4$  in  $\tau_4$  is the function of  $\tau_4$  is the funct

1.3 Assignment Project Exam Help

The coercion of values should be coherent. This means that, if there are two ways to coerce a value to a value of a supertype, both coercions have to yield the same result.

For example, let u string, with coerchttps://eduassistpro.github.io/

intToFloat :: Int  $\rightarrow$  Float intToString :: Int  $\rightarrow$  String  $floatToString <math>\land$ : Float  $\rightarrow$  Str.

## Add WeChat edu\_assist\_pro

On first sight, this looks like a reasonable relationship. It is not coherent, ho there are two coercion function from *Int* to *String*: the provided function *intToString*, but also *intToFloat* composed with *floatToString*. Unfortunately, applied to the number 3, for example, one would result in the string "3", the other in "3.0"

One reason why type promotion in C can be so tricky is exactly that it is not coherent in this way.

#### 1.4 Variance

If we add subtyping to MinHS, one question that arises is how the subtyping relationship interacts with our type constructors. For example, if  $Int \leq Float$ , what about pairs, sums and function over these types? How do they relate to each other?

For pairs and sums, the answer is quite straight forward. Obviously, given a coercion function intToFloat, we can easily define coercion functions on pairs and sums:

```
p1 :: (\operatorname{Int} \times \operatorname{Int}) \to (\operatorname{Float} \times \operatorname{Float})
p1 (x, y) = (\operatorname{int} ToFloat x, \operatorname{int} ToFloat y)
p2 :: (\operatorname{Int} \times \operatorname{Float}) \to (\operatorname{Float} \times \operatorname{Float})
p2 (x, y) = (\operatorname{int} ToFloat x, y)
...
```

<sup>&</sup>lt;sup>2</sup>More about that later

```
s1 :: (Int + Int) \rightarrow (Float + Float)
s1 x = \mathbf{case} \ x \mathbf{of}
                  lnL v \rightarrow intToFloat v
                  InR v \rightarrow intToFloat v
```

This means that, if two types  $\tau_1$  and  $\tau_2$  are subtypes of  $\sigma_1$  and  $\sigma_2$ , respectively, then pairs of  $\tau_1$ and  $\tau_2$  are also subtypes of pairs of  $\sigma_1$  and  $\sigma_2$  and the same is true for sums. More formally, we

$$\tau_1 \le \rho_1 \qquad \tau_2 \le \rho_2$$

### Assignment Project Exam Help

Given that the pair as ious way, it is easy to be trick is not the case. https://eduassistpro.github.io/
Consider functi type  $Float \rightarrow Int$  is required, would it be ok to provide a functio  $t \rightarrow Int instead?$ Considering that the type Int is more restricted than the ty which only works on the "male" vpe Int it also is U hat a function back to our second example, if we need a function to process any graph, th only works on trees (and maybe relies on the fact that there are no cycles in a tree) is clearly not sufficient. We are also not able to define a coercion function in terms of our coercion function intToFloat:

```
c :: (Int \rightarrow Float) \rightarrow (Float \rightarrow Float)
```

The other direction, however, is actually quite easy:

```
c' :: (Float \rightarrow Float) \rightarrow (Int \rightarrow Float)
c' f = \mathbf{let} g x = f (intToFloat x)
```

Therefore, somewhat surprisingly, we have  $({\tt Float} \to {\tt Float}) \leq ({\tt Int} \to {\tt Float})$ .

So, what about the result type of a function: is  $Int \rightarrow Int$  as subtype of  $Int \rightarrow Float$ , vice versa, or are these types not in a subtype relationship at all? If we need a function which returns a Float and get one that returns an Int, it is not a problem, since we can easily convert that Int to a Float. Similarly, if we need a function which returns a graph, and we get a tree, it is ok as a tree is a special case of a graph and can be converted to the graph representation:

$$\begin{array}{ll} c'' & :: (\mathtt{Int} \, \to \, \mathtt{Int}) \, \to \, (\mathtt{Int} \, \to \, \mathtt{Float}) \\ c'' \, f = \, \mathbf{let} \, g \, x \, = \, intToFloat \, (f \, x) \, \mathbf{in} \, g \end{array}$$

To summarise, the subtype relationship on functions over Int and Float is as follows (of course, you can substitute any type  $\tau$  for Int,  $\rho$  for Float here, as long as  $\tau \leq \rho$ ):

$$\begin{array}{ccc} \operatorname{Int} \to \operatorname{Int} & \longmapsto & \operatorname{Int} \to \operatorname{Float} \\ & & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & \\ & & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & \\ & & \\ & & \\ & \\ & \\ & & \\ & \\ & & \\ & \\ & \\ & \\ & & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\$$

The subtype propagation rule for function types expresses exactly the same relationship:

$$\frac{\tau_1 \le \rho_1 \qquad \tau_2 \le \rho_2}{(\rho_1 \to \tau_2) \le (\tau_1 \to \rho_2)}$$

Another example of a type which interacts with subtyping in a non-obvious manner are updateable arrays and reference types. To understand what is happening, let us have a look at Haskell-style updatable references. We have the following basic operations on this type:

newIORef :: a →
writeIORef :: a →
https://eduassistpro.github.io/

All other operations can be expressed in terms of these three operations.

The question now is, if  $\tau \leq \sigma$ , what is the subtype relationship between IORef  $\tau$  and IORef  $\sigma$ ? To check whether, So Sekani II, IDRef Int  $\leq$  To fee Float (left us have adolt at vine paper if we apply write IORef (L.S.: Float) to an IORef Int instead of an IORef Float. Clearly, this would not work, as the floating point ville can't be stored in an Interest call it would be okay the other way around. If we write IORef (1.: Int.) apply to an IORef Float, it would be fine, since we could first coerce the value to a Float and store the result in the Float reference. This seems to suggest that I

However, if we assembly the standard of the reading of the reading

we could apply it to an JORef int and the result This means that I mple result at all: when a reference of a certain type is required, we cannot substitu or supertype.

We encounter exactly the same situation with updatable arrays. In fact, in Java, the language allows subtyping for arrays, at the cost of dynamic checks, as this violates type safety.

Type constructors like product and sum, which leave the subtype relationship intact, as called *covariant*, type constructors which reverse the relationship, lie the function type in its first argument, are called *contravariant*, and type constructors like IORef, which do not imply a subtype relationship at all are called *invariant*.
